

with his model.

2.3 Parsimony

time series

Since all models are wrong

Exploring forecasting retail sales at scale

Benedict Au, Brea Beals, Mark Roberts, Yannik Kumar

2.4 Worrying Selectively

Since all models are wrong the scientist must be alert to what is importantly wrong. It is inappropriate to be concerned about mice when there are tigers abroad.

allow him to compare reality. In this way eventually achieve better such words as *expectation* mathematical solutions relevance to reality

3. Fisher

With these ideas in as a scientist, using forecasting during his Station.

3.1 Rothamsted

In 1919, Fisher had of working under Ka

1

what classes of models perform best across categories/items?

2

do we lose accuracy adopting a hierarchical approach? Are we ok with this tradeoff?

3

does cross-validation give us the same ranking of models?

4

how much data do we need to make a decent forecast?

BARK

4 categories

20 items

Models

- > Ran all models below for all 20 items for both daily and weekly seasonality where appropriate
- > All models were written as functions so this project can easily be expanded to additional product items

- > **Simple forecasting methods:**

Average, Naive, Seasonal Naive

- > **ARIMA models:** ARIMA, Seasonal ARIMA, and ARFIMA

- > **OLS:** using trend, year, month, day of week, snap benefits, prices, and cultural/religious events

- > **Holt-Winters:**

Additive Method

- > **STL**

- > **Prophet**

- > **TBATS**

- > **ARCH + GARCH** combination

- > **Neural Networks**

- > **Hierarchical Modeling:**

Top-down (ARIMA and ETS)
and Middle-out (ARIMA and ETS)

Selection criteria

- > Separated data into train and test sets, where test set was the last 28 days
- > **Mean absolute scaled error (MASE)** as measure of forecast accuracy
 - > Scale free error metric
 - > Well suited for intermittent-demand series because it never gives infinite or undefined values
- > **Ljung-Box Test** on residuals as a test for autocorrelation
 - > Used p-value to compare models to see which had residuals resembling white noise

work

Feature extraction

- > specific to regression model:

 - dummy-coded days, months and added trend feature

- > for autoregressive models:

 - dummy-coded event-types, and SNAP promotions

Forecasting

1

what classes of models perform best across categories/items?

- > Autoregressive neural networks! All you need is one hidden layer and <20 neurons and you can whiten your stubbornest residuals

2

do we lose accuracy adopting a hierarchical approach? Are we ok with this tradeoff?

- > Surprisingly no. Hierarchical approaches using ETS (both top-down and middle-out) often worked better than models fitted to individual items. A regularizing influence?

3

does cross-validation give us the same ranking of models?

- > Yes.

4

how much data do we need to make a decent forecast?

- > Two years of data seems to be sufficient.

work

Future work

- > Model inter-dependencies (complements vs substitutes) among products via estimating cross-price elasticity
- > Extend our methodology and incorporate more items (do the same results hold when the number of items is 1000+?)
- > Try to incorporate more external regressors (outside those provided in the dataset)
